[LAMBDA (ORIGFN MODERNWINDOWFN ANYWHERE TITLEPROPORTION) ; Edited 24-Jun-2021 14:53 by rmk:
;; ORIGFN is either a function that creates windows of a given type (e.g. SNAPW or ADD-EXEC) or the known BUTTONEVENTFN of a class of windows.
;; Moves ORIGNFN to a new name, prefixed with MODERNORIG-.
;; If MODERNWINDOWFN is given, then that replaces the original definition of ORIGFN, and presumably knows how to call the renamed ORIGFN under the right circumstances. This is typically the case where ORIGFN is a window creator.
;; Otherwise, ORIGFN is taken to be the BUTTONEVENTFN for a class of windows, and its new definition is defaulted to one that maps left-clicks in appropriate areas into modern window operations. If not in appropriate areas, then the renamed ORIGNFN is called to give the original button behavior.
;; If ANYWHERE, moving will happen for any click not in one of the shaping corners.
;; The renamed function has arguments in addition to WINDOW: the new name for the original function, if MODERNWINDOFN is provided, and the value specified here for ANYWHERE.
```

```
(CL:WHEN (GETD ORIGFN)
  ;; If ORIGFN is defined, then presumably the file containing ORIGFN (e.g. sketch) was loaded before MODERNIZE (if we are being called on our load), and we can rearrange things. But if ORIGFN is not defined, then there is really nothing to do. The package loader itself should call MODERNWINDOW.SETUP if we are defined when it is loaded.

 ; Edited 16-Oct-2021 15:25 by rmk:

;; WINDOW is the window that received the click and that should be passed through to the original function, if we don't pick it off here.

;; However, that window may be an auxiliary window (an attached menu? or a lower split-pane in Tedit) whose region and title intuitively should not
; be used to control shaping and moving behavior. That behavior is determined by the CORNERREGION and TITLE parameters.;; If CORNERREGION is given, we know that there are two windows in play. In that case also TOPMARGIN tells us the hotband at the top of the
; cornerregion where the move/shaping click is recognized, T to mean that it has an ordinary title bar..;; For windows without a top margin, the shape/move region is MODERN-WINDOW-MARGIN points below the top, in the clipping region of the
; window.;; Changed to use Wborder for the top region of an untitled window instead of MODERN-WINDOW-MARGIN. Maybe it should be 2 times the border
; width in that case, and the MODERN-WINDOW-MARGIN separately defines the rectangle that constitutes a corner.

(LET (CORNER ATTACHEDREGION)

(IF CORNERREGION

THEN ; Caller tells us whether the corner window has a title.
