Description/Introduction

Masterscope has been modified to provide for analysis of files created under the Koto or Lyric/Medley release of LOOPS. A full explanation of Masterscope can be found in the *Lisp Library Modules Manual*. In addition to the relations explained there, LOOPS defines the relations described in this chapter.

Note: Masterscope data base files created under Buttress Loops will not function properly in this release. Those data base files will have to be recreated.

Installation/Loading Instructions

- Load MASTERSCOPE from your Lyric/Medley library floppies according to its loading instructions. This should load the compiled files MASTERSCOPE, MSANALYZE, and MSPARSE.
- Load LOOPSMS.DFASL from wherever you installed the LOOPS Library Modules. This should load versions of MASTERSCOPE and MSPARSE that extend Masterscope to handle LOOPS constructs.

Relations

	LOOPS defines the following relations:		
Name	Туре	Description	
SEND	Relation	Collects all places where the method is sent.	
SEND SELF	Relation	Collects all places where the method is sent to <i>self</i> .	
SEND NOTSELF	Relation	Collects all places where the method is sent to an object other than <i>self</i> .	
GET	Relation	Locates all places where the value of an instance variable is retrieved.	
GET CV	Relation	Locates all places where the value of a class variable is retrieved.	
PUT	Relation	Locates all places where the value of an instance variable is set.	
PUT CV	Relation	Locates all places where the value of a class variable is set.	
IMPLEMENT	Relation	Locates all methods that specialize the given selector.	
SPECIALIZE	Relation	Locates all methods that specialize the given selector and use \leftarrow Super in the body of the method.	
OVERRIDE	Relation	Locates all methods that specialize the given selector and do not use \leftarrow Super in the body of the method.	

USE IV	Relation	Used with an instance variable name to locate all places where the instance variable is used in a GET or PUT.
USE CV	Relation	Used with a class variable name to locate all places where the class variable is used in a GET or PUT.
USE OBJECT	Relation	Used with an object name to locate all places where the object is used.
SEND		[Relation]
Purpose/Behavior:	Used betwee method is s	een method names and selectors to collect all places where the sent. For example, the form
	. WHO IS	SENT BY 'Helicopter.Move
	works, but	
	. WHO IS	SENT BY Move
	does not w	ork.
Example:	The followi New .	ng command allows you to edit all code that sends the message
	. EDIT A	LL WHO SEND New
SEND SELF		[Relation]
Purpose/Behavior:	Used betwee method is s	een method names and selectors to collect all places where the sent to <i>self</i> . Places where
	$(\leftarrow$ self me	thodName)
	is found are	e collected, while places where
	$(\leftarrow otherInst$	stance methodName)
	is found are	e not.
Example:	The followin Clear to se	ng command allows you to edit all code that sends the message If.
	. WHO SE	NDS SELF Clear
SEND NOTSELE		[Relation]
Purpose:	Same as S an object o	END SELF, except the only places where the message is sent to the than self.
Example:	The followin instance ot	ng allows you to edit all code that sends the message Clear to any her than <i>self</i> .
	. SHOW A	LL WHO SEND NOTSELF Clear
OFT		
<u>uci</u>		
Purpose:	Used with a the instance SELF and I	an instance variable name to locate all places where the value of e variable is retrieved. This relation can be used along with the NOTSELF modifiers.

	Example:	This command allows you to edit all code that gets the value of the instance variable width from an instance other than self and the value of the instance variable height from <i>self</i> .
		. SHOW ALL WHO GET NOTSELF width AND GET SELF height
GET CV		[Relation]
	Purpose:	Same as GET , except that GET CV locates places where the value of the class variable is retrieved. This relation can be used with the SELF and NOTSELF modifiers.
	Example:	This command allows you to edit all code that accesses the value of the class variable height of <i>self</i> .
		. SHOW ALL WHO GET CVSELF height
PUT		[Relation]
	Purpose:	Used with an instance variable name to locate all places where the value of the instance variable is set. This relation can be used along with the SELF and NOTSELF modifiers.
	Example:	This command allows you to edit all code that sets the value of the instance variable width.
		. EDIT ANY WHO PUT width
PUT CV		[Relation]
	Purpose:	Same as PUT , except locates places where a specified class variable is set. This relation can be used along with the SELF and NOTSELF modifiers.
	Example:	This command list all the sections of code that set the value of the class variable width for an instance other than <i>self</i> .
		. WHO PUTS CV NOTSELF width
IMPLEMENT		[Relation]
	Purpose:	Used with a method name to locate all methods that specialize the given selector.
	Example:	This returns a list of classes where the method Clear is defined.
		. WHO IMPLEMENTS Clear
SPECIALIZE		[Relation]
	Purpose:	Used with a method name to locate all methods that specialize the given selector and use \leftarrow Super in the body of the method.
	Example:	This command allows you to edit all the methods that are specializations of Clear and use the \leftarrow Super form.
		. EDIT ANY WHO SPECIALIZE Clear
OVERRIDE		[Relation]
	Purpose:	Like SPECIALIZE above, except it locates all methods that specialize the given selector and \leftarrow Super is not used in the body of the method.

	Example:	This command allows you to edit all the specializations of Clear that do not make use of the \leftarrow Super form.
		. EDIT ALL WHO OVERRIDE Clear
USE IV		[Relation]
	Purpose:	Used with an instance variable name to locate all places where the instance variable is used in a Get or Put . It is equivalent to using the relation form of GET IVName or PUT IVName .
	Example:	This command allows you to edit all code that either sets or accesses the instance variable width .
		. EDIT ANY WHO USE THE IV width.
USE CV		[Relation]
	Purpose:	Used with a class variable name to locate all places where the class variable is used in a Get or Put . It is equivalent to using the relation form: GET CV CVName OR PUT CV CVName .
	Example:	This command allows you to edit all code where the class variable commonWindow is either set or accessed.
		. EDIT ANY WHO USE THE CV commonWindow
USE OBJECT		[Relation]
	Purpose	Uses an object name to locate all places where the object is used.
	Example	This command returns a list of all code where the object Window is used.
		. WHO USES THE OBJECT Window??

Limitations

Masterscope has several limitations:

- Names of methods must be quoted when used with Masterscope; for example, the method name Helicopter.Move must be entered as 'Helicopter.Move.
- The following expression will not find a call to GetValue when in a method:
 - . WHO CALLS GetValue

Masterscope does not record calls to **GetValue** and **PutValue** explicitly; it records them under the Get- relation along with calls of the form

(\leftarrow foo Get 'bar)

Similarly, the following functions are recorded under relations instead of their names:

GetClassValue PutClassValue GetClassIV PutClassIV

Put CV Get IV Put IV

Get CV

If you want to find the explicit calls to Get/PutValue, use

- . WHO GETS ANY AND NOT SENDS Get
- Masterscope currently assumes calls to **GetValue** and similar accessors are accessing instance variables; i.e.,

(GetValue foo 'bar)

records an access to the instance variable **bar**. This is not necessarily the case; **bar** could also be a class variable.

 The methods and functions that create class and instance variables populate the appropriate **PUT NOTSELF** relations. For example, a function that does

(\leftarrow (\$ foo) AddCV 'bar)

will be found by the query

. WHO PUTS CV NOTSELF 'bar

An exception occurs with the generalized **Add** and **Delete** method. For example,

(\$ foo) Add 'IV 'bar)

will not be noticed as accessing the instance variable bar.

Also, the templates for methods and functions that accept property lists generally only notice the first property. For example,

 $((\leftarrow (\$ foo) NewWithValues '((bar baz chain link sausage)))$

notices **baz** as a property, not a link.
